### 8.1 Cellular Respiration

**Cellular respiration** is a cellular process that breaks down nutrient molecules produced by photosynthesizers with the concomitant production of ATP.

It consumes oxygen and produces carbon dioxide ( $\text{CO}_2$ ).

- Cellular respiration is an **aerobic** process.

It usually involves the complete breakdown of glucose to  $\text{CO}_2$  and  $\text{H}_2\text{O}$ .

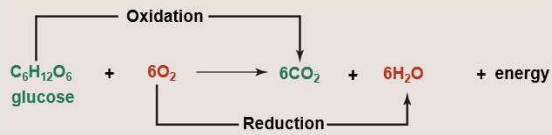

- Energy is extracted from the glucose molecule:
  - Released step-wise
  - Allows ATP to be produced efficiently
- Oxidation-reduction enzymes include  $\text{NAD}^+$  and  $\text{FAD}$  as coenzymes.

8-3

## Cellular Respiration

### Cellular Respiration (1)

Electrons are removed from substrates and received by oxygen, which combines with  $\text{H}^+$  to become water.

Glucose is oxidized and  $\text{O}_2$  is reduced.

### Cellular Respiration (3)

#### **NAD<sup>+</sup>** (nicotinamide adenine dinucleotide)

- A coenzyme of oxidation-reduction, it is:
  - Oxidized when it gives up electrons
  - Reduced when it accepts electrons
  - Each NAD<sup>+</sup> molecule is used over and over again.

#### **FAD** (flavin adenine dinucleotide)

- Also a coenzyme of oxidation-reduction
- Sometimes used instead of NAD<sup>+</sup>
- Accepts two electrons and two hydrogen ions ( $\text{H}^+$ ) to become  $\text{FADH}_2$

## Cellular Respiration

### Phases of Cellular Respiration (1)

Cellular respiration includes four phases:

- **Glycolysis** is the breakdown of glucose into two molecules of pyruvate.
  - It occurs in the cytoplasm.
  - ATP is formed.
  - It does not utilize oxygen (anaerobic).
- **Preparatory (prep) reaction**
  - Both molecules of pyruvate are oxidized and enter the matrix of the mitochondria.
  - Electron energy is stored in NADH.
  - Two carbons are released as  $\text{CO}_2$  (one from each pyruvate).

---

---

---

---

---

---

### Phases of Cellular Respiration (2)

#### Citric acid cycle

- Occurs in the matrix of the mitochondrion and produces NADH and  $\text{FADH}_2$
- A series of reactions, releases 4 carbons as  $\text{CO}_2$
- Turns twice per glucose molecule (once for each pyruvate)
- Produces two immediate ATP molecules per glucose molecule

---

---

---

---

---

---

#### Electron transport chain (ETC)

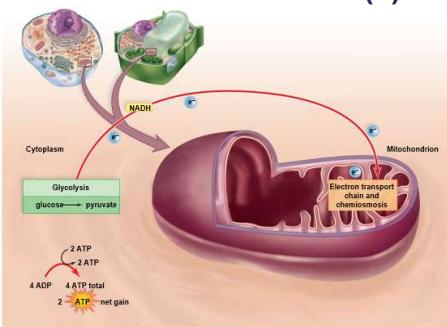

- A series of carriers on the cristae of the mitochondria
- Extracts energy from NADH and  $\text{FADH}_2$
- Passes electrons from higher to lower energy states
- Produces 32 or 34 molecules of ATP by chemiosmosis

## Cellular Respiration

### 8.2 Outside the Mitochondria: Glycolysis

**Glycolysis** occurs in cytoplasm outside mitochondria.

It consists of a series of 10 reactions, each with its own enzyme.

Energy Investment Step:

- Two ATP are used to activate glucose.
- Glucose splits into two G3P molecules.

Energy Harvesting Step:

- Oxidation of G3P occurs by removal of electrons and hydrogen ions.
- Two electrons and one hydrogen ion are accepted by NAD<sup>+</sup> resulting in two NADH.
- Four ATP are produced by **substrate-level phosphorylation**.
  - An enzyme passes a high-energy phosphate to ADP, making ATP.
- There is a net gain of two ATP (4 ATP produced - 2 ATP consumed).
- Both G3Ps convert to pyruvates.

# **Cellular Respiration**

## Cellular Respiration

**8.3 Outside the Mitochondria: Fermentation**

**Pyruvate** is a pivotal metabolite in cellular respiration.

If O<sub>2</sub> is not available to the cell, **fermentation**, an anaerobic process, occurs in the cytoplasm.

- During fermentation, glucose is incompletely metabolized to lactate, or to CO<sub>2</sub> and alcohol (depending on the organism).

If O<sub>2</sub> is available to the cell, pyruvate enters the mitochondria for aerobic respiration.

8-24

# **Cellular Respiration**

## Outside the Mitochondria: Fermentation (1)

**Fermentation** is an *anaerobic* process that reduces pyruvate to either lactate or alcohol and  $\text{CO}_2$

NADH transfers its electrons to pyruvate.

Alcoholic fermentation, carried out by yeasts, produces carbon dioxide and ethyl alcohol.

- Used in the production of alcoholic spirits and breads

Lactic acid fermentation, carried out by certain bacteria and fungi, produces lactic acid (lactate).

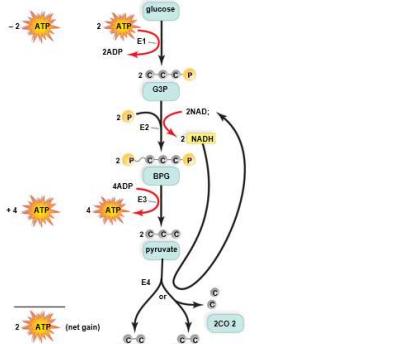

- Used commercially in the production of cheese, yogurt, and sauerkraut.

Other bacteria produce chemicals anaerobically, including isopropanol, butyric acid, propionic acid, and acetic acid.

## Fermentation

### Description

8-26

## Outside the Mitochondria: Fermentation (2)

## Advantages

- Provides a quick burst of ATP energy for muscular activity
    - When muscles are working vigorously for a short period of time, lactic acid fermentation provides ATP.

### Disadvantages

- Lactate and alcohol are toxic to cells.
  - Lactate changes pH and causes muscles to fatigue.
    - Oxygen debt
  - Yeast die from the alcohol they produce by fermentation.

### Efficiency of Fermentation

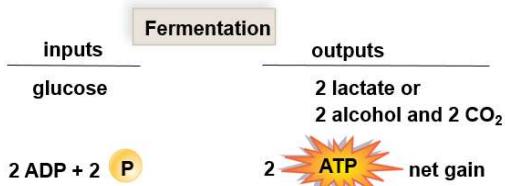

- Two ATP produced per glucose of molecule during fermentation is equivalent to 14.6 kilocalorie.
  - Complete oxidation of glucose can yield 686 kilocalorie.
    - Efficiency is 2.1% of total possible for glucose breakdown.
  - Only 2 ATP per glucose are produced, compared to 36 or 38 ATP molecules per glucose produced by cellular respiration.

### 8.4 Inside the Mitochondria

#### The preparatory (prep) reaction

- It connects glycolysis to the **citric acid cycle**.
- End product of glycolysis, pyruvate, enters the mitochondrial matrix.
- Pyruvate is converted to a 2-carbon acetyl group.
  - Attached to Coenzyme A to form acetyl-CoA
  - Electrons picked up (as hydrogen atom) by NAD<sup>+</sup>, producing NADH
  - CO<sub>2</sub> is released and transported out of mitochondria into the cytoplasm.
  - Occurs twice per glucose molecule

# **Cellular Respiration**

## Inside the Mitochondria (2)

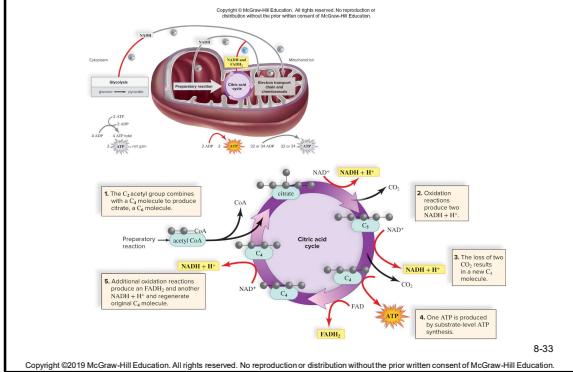

## Citric Acid Cycle

- Also called the Krebs cycle
  - Occurs in the matrix of mitochondria
  - Begins with the addition of a 2-carbon acetyl group (from acetyl-CoA) to a 4-carbon molecule (oxaloacetate), forming a 6-carbon molecule (citric acid)
  - NADH and FADH<sub>2</sub> capture energy rich electrons
  - ATP formed by substrate-level phosphorylation
  - Turns twice for one glucose molecule (once for each pyruvate)
  - Produces 4 CO<sub>2</sub>, 2 ATP, 6 NADH, and 2 FADH<sub>2</sub> per glucose molecule

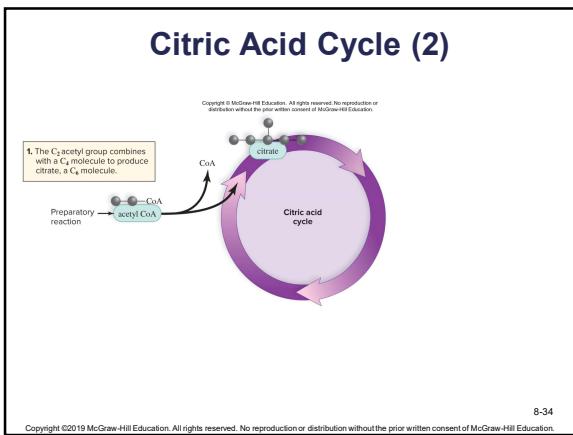

8-32

### Inside the Mitochondria (4)

#### Electron Transport Chain (ETC)

Location:

- Eukaryotes – cristae of the mitochondria
- Aerobic prokaryotes – plasma membrane

Series of carrier molecules:

- Pass energy-rich electrons successively from one to another
- Complex arrays of protein and **cytochrome**
  - Proteins with heme groups with central iron atoms

The electron transport chain:

- Receives electrons from NADH & FADH<sub>2</sub>
- Produces ATP by oxidative phosphorylation

Oxygen final electron acceptor:

- Combines with hydrogen ions to form water

8-40

---

---

---

---

---

---

---

---

### Inside the Mitochondria (5)

The fate of the hydrogens

- Hydrogens from NADH deliver enough energy to make 3 ATPs.
- Those from FADH<sub>2</sub> have only enough for 2 ATPs.
- "Spent" hydrogens combine with oxygen.

Recycling of coenzymes increases efficiency.

- Once NADH delivers hydrogens, it returns (as NAD<sup>+</sup>) to pick up more hydrogens.
- However, hydrogens must be combined with oxygen to make water.
- If O<sub>2</sub> is not present, NADH cannot release H<sup>+</sup>.
- It is no longer recycled back to NAD<sup>+</sup>.

8-41

---

---

---

---

---

---

---

---

### Inside the Mitochondria (6)

The electron transport chain complexes pump H<sup>+</sup> from the matrix into the intermembrane space of the mitochondrion.

H<sup>+</sup> therefore becomes more concentrated in the intermembrane space, creating an electrochemical gradient.

ATP synthase allows H<sup>+</sup> to flow down its gradient.

The flow of H<sup>+</sup> drives the synthesis of ATP from ADP and inorganic phosphate by ATP synthase.

This process is called **chemiosmosis**.

- ATP production is linked to the establishment of the H<sup>+</sup> gradient.
- ATP moves out of mitochondria and is used for cellular work.
- It can be broken down to ADP and inorganic phosphate.
- These molecules are returned to the mitochondria for more ATP production.

8-43

### Inside the Mitochondria (7)

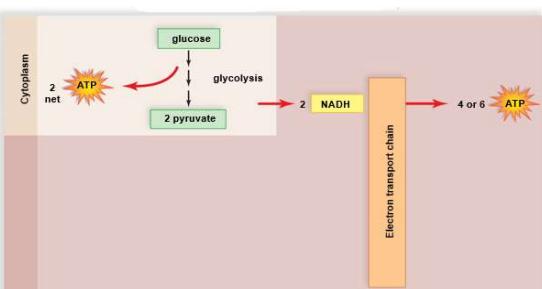

#### Energy yield from glucose metabolism

- Net yield per glucose
  - From glycolysis – 2 ATP
  - From citric acid cycle – 2 ATP
  - From electron transport chain – 32 or 34 ATP
- Energy content
  - Reactant (glucose) 686 kilocalorie
  - Energy yield (36 ATP) 263 kilocalorie
  - Efficiency is 39%
  - Rest of energy from glucose is lost as heat

# **Cellular Respiration**

## 8.5 Metabolism

## Foods

- Sources of energy rich molecules
  - Carbohydrates, fats, and proteins

Degradative reactions (**catabolism**) break down molecules.

- Tend to be exergonic (release energy)

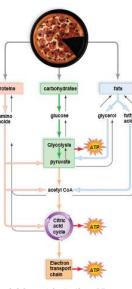

Synthetic reactions (**anabolism**) build molecules.

- Tend to be endergonic (consume energy)

8-49

## The Metabolic Pool Concept

[Jump to The Metabolic Red Concept Lens Description](#) 8.50

Copyright 2010 McGraw-Hill Education. All rights reserved. No reproduction or distribution without the prior written consent of McGraw-Hill Education.

## Metabolic Pool (1)

Glucose is broken down in cellular respiration.

Fat breaks down into glycerol and three fatty acids.

Amino acids break down into carbon chains and amino groups.

- **Deamination** ( $\text{NH}_2$  removed) occurs in the liver.
    - Results in poisonous ammonia ( $\text{NH}_3$ )
    - Quickly converted to urea
  - Different *R*-groups from amino acids are processed differently.
  - Fragments enter respiratory pathways at many different points.

8-51

8-31

## Cellular Respiration

### Metabolic Pool (2)

All metabolic compounds are part of the metabolic pool.

Intermediates from respiratory pathways can be used for **anabolism**.

Anabolism (synthetic reactions of metabolism):

- Carbohydrates
  - Start with acetyl-CoA
  - Basically reverses glycolysis (but different pathway)
- Fats
  - G3P converted to glycerol
  - Acetyl groups are connected in pairs to form fatty acids.

8-52

---

---

---

---

---

---

### Metabolic Pool (3)

Anabolism:

- Proteins
  - They are made up of combinations of 20 different amino acids.
  - Some amino acids (11) can be synthesized by adult humans.
  - However, other amino acids (9) cannot be synthesized by humans.
    - Essential amino acids
    - Must be present in the diet

### The Energy Organelles Revisited (1)

Similarities between photosynthesis and cellular respiration:

- Use of membrane
  - Chloroplasts' inner membrane forms thylakoids.
  - Mitochondria's inner membranes form cristae.
  - Electron transport chain
    - ETC is located on thylakoid membranes and cristae.
    - In photosynthesis, electrons passed to ETC were energized by the sun.
    - In mitochondria electrons, energized electrons were removed from glucose.
    - In both, ETC establishes an electrochemical gradient of H<sup>+</sup> with ATP production by chemiosmosis.
- Enzymes
  - In chloroplast, stroma has Calvin cycle enzymes.
  - In mitochondria, matrix contains enzymes of citric acid cycle.

---

---

---

---

---

---

## Cellular Respiration

### Flow of Energy

Energy flows from the sun, through chloroplasts to carbohydrates, and then through mitochondria to ATP molecules.

- This flow of energy maintains biological organization at all levels from molecules to organisms to the biosphere.
- Some energy is lost with each chemical transformation.
  - Eventually all solar energy captured is lost.
  - All life depends on solar energy input.

Chemicals cycle within natural systems.

- Chloroplasts produce oxygen and carbohydrates, which are used by mitochondria to generate energy for life.

Chloroplasts and mitochondria allow energy flow through organisms and permit chemical cycling.
